STA437 Assignment #3

Problem 1

(a) Solution:

$$S = V\Lambda V^{T} = \begin{pmatrix} \mathbf{v}_{1} & \cdots & \mathbf{v}_{p} \end{pmatrix} \begin{pmatrix} \lambda_{1} & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & \lambda_{p} \end{pmatrix} \begin{pmatrix} \mathbf{v}_{1}^{T} \\ \vdots \\ \mathbf{v}_{p}^{T} \end{pmatrix}$$

$$= \lambda_{1} \mathbf{v}_{1} \mathbf{v}_{1}^{T} + \lambda_{2} \mathbf{v}_{2} \mathbf{v}_{2}^{T} + \cdots + \lambda_{p} \mathbf{v}_{p} \mathbf{v}_{p}^{T}$$

$$LL^{T} = \begin{pmatrix} \lambda_{1}^{\frac{1}{2}} \mathbf{v}_{1} & \cdots & \lambda_{r}^{\frac{1}{2}} \mathbf{v}_{r} \end{pmatrix} \begin{pmatrix} \lambda_{1}^{\frac{1}{2}} \mathbf{v}_{1}^{T} \\ \vdots \\ \lambda_{r}^{\frac{1}{2}} \mathbf{v}_{r}^{T} \end{pmatrix}$$

$$= \lambda_{1} \mathbf{v}_{1} \mathbf{v}_{1}^{T} + \lambda_{2} \mathbf{v}_{2} \mathbf{v}_{2}^{T} + \cdots + \lambda_{r} \mathbf{v}_{r} \mathbf{v}_{r}^{T}$$

Note that r < p.

We claim that $\operatorname{diag}(S) = \operatorname{diag}(\Psi + LL^T)$, so

$$\Psi = \operatorname{diag}(\Psi) = \operatorname{diag}(S - LL^{T}) = \operatorname{diag}(\lambda_{r+1} \nu_{r+1} \nu_{r+1}^{T} + \dots + \lambda_{p} \nu_{p} \nu_{p}^{T})$$

Observe that the product of column vector v_{r+1} and its transpose v_{r+1}^T generates a p-by-p matrix whose i-th diagonal line element is $v_{i(r+1)}^2$ and $v_{i(r+1)}$ is the i-th element in vector v_{r+1}

Therefore the i-th element in diagonal matrix Ψ , where i is any integer from 1 to p:

$$\psi_{ii} = \sum_{j=r+1}^{p} \lambda_j v_{ij}^2.$$

(b) Proof:

Since the diagonal elements of $D=\Psi+LL^T-S$ are 0 so we need only consider the off-diagonal elements of LL^T-S , which is equal to $-\lambda_{r+1} v_{r+1} v_{r+1}^T-\cdots-\lambda_p v_p v_p^T$.

We can see $LL^T - S$ as the sum of a bunch of matrices. And for each matrix, we take $-\lambda_{r+1} v_{r+1} v_{r+1}^T$ as example, we are interested in the sum of squares of its off-diagonal part, which can be expressed as:

$$\lambda_{r+1}^2 \cdot \sum_{i,j < r+1, i \neq j} v_{i(r+1)}^2 v_{j(r+1)}^2$$

And if we can show such part is no greater than λ_{r+1}^2 , i.e., $\sum_{i,j < r+1, i \neq j} v_{i(r+1)}^2 v_{j(r+1)}^2 \leq 1$, then the desired inequation to prove is nothing but adding a bunch of similar inequations up.

Recall that V is an orthogonal matrix, so that any of its column v_k is an orthogonal unit vector. Therefore, $\sqrt{\sum_{i=1}^p v_{ik}^2} = 1$. And this is a sum of p non-negative terms which are all not greater than 1. Then for each term, we multiple it by another non-negative term no greater than 1. Consequently, the sum of these new p terms are no greater than 1 since each term becomes smaller (or stays equivalent).

So $\sum_{i=1,j=1}^{p} v_{i(r+1)}^2 v_{j(r+1)}^2 \le 1$. And our previous version has already extracted the diagonal elements, so the sum should be even smaller with:

$$\sum_{i,j < r+1, i \neq j}^{p} v_{i(r+1)}^{2} v_{j(r+1)}^{2} \le \sum_{i=1,j=1}^{p} v_{i(r+1)}^{2} v_{j(r+1)}^{2} \le 1.$$

Both sides multiple by λ_{r+1}^2 , then sum up from r+1 to p, and finally we are done, have the following result:

$$\sum_{i=1}^{p} \sum_{j=1}^{p} d_{ij}^{2} \le \lambda_{r+1}^{2} + \dots + \lambda_{p}^{2}.$$

(c) Solution:

The LHS of result in part (b) is the total variations.

- We start from t = p, calculate $\sum_{i=1}^{k} \sum_{j=1}^{k} d_{ij}^2$.
- Calculate the ratio of variations that these t factors can explain, if this proportion is large enough, e.g. we set the critical level at 90% or 80%.
- Iterate on t, each time t := t 1.
- If the proportion drops below the critical level, keep the previous t as that the number of factors.

Problem 2

(a) Solution:

```
1 > exam <- scan("marks.txt",what=list(0,0,0,0,0))
 2 Read 88 records
 3 > mec <- exam[[1]]
4 > vec <- exam[[2]]
 5 > alg <- exam[[3]]
6 > ana <- exam[[4]]
7 > sta <- exam[[5]]
8 > data <- cbind(mec,vec,alg,ana,sta)</pre>
9 > factanal(data,factors=1)
10
11 Call:
12 factanal(x = data, factors = 1)
13
14 Uniquenesses:
15
     mec
                              sta
         vec
                 alg
                       ana
16 0.641 0.555 0.158 0.403 0.476
17
18 Loadings:
       Factor1

29
30 Test of the hypothesis that 1 factor is sufficient.
31 The chi square statistic is 8.65 on 5 degrees of freedom.
32 The p-value is 0.124
```

• The p-value of this model fitting the data adequately is 0.124 > 0.05, which is not very low, so we fail to reject. Hence the single factor model fits the data somewhat adequately.

(b) Solution:

The variable alg has the heaviest loading, so it is the most important one.

Graphical Model (from simple analysis) MECHI ANA VECT STAT

• As the graphical dependence model indicates, the alg variable is dependent with all other variables, it is involved in the most variations, thus making it such important one.

(c) Solution:

```
1 > factanal(data, factors=2)
 2
 3 Call:
 4 factanal(x = data, factors = 2)

25 The p-value is 0.785
```

- The p-value of two factors model is higher than that of single factor model, which is an improvement.
- The loadings of the default two factors model are not understandably easy to interpret. And in fact, the rotation it used was varimax.
- So we do the same process but with different rotations none and promax.

```

52
53 Test of the hypothesis that 2 factors are sufficient.
54 The chi square statistic is 0.07 on 1 degree of freedom.
55 The p-value is 0.785
```

- As the result shows, rotation promax seems to generate a possibly interpretable set of loadings with:
 - loading 1: the marks of subjects Algebra, Analysis and Statistics.
 - loading 2: the marks of subjects Mechanics and Vectors.
- none rotation has two sets of loadings, but it's not practically understandable. (Maybe loading 1 indicates the general level of all 5 subjects, loading 2 indicates the sum of Mechanics and Vectors minus the sum of Analysis and Statistics. And this does not make much sense in real life.)

Problem 3

(a) Solution:

```
1 > x <- scan("crabs.txt", skip=1, what=list("c", "c", 0, 0, 0, 0, 0, 0))
 2 Read 200 records
 3 > colour <- x[[1]]
4 > sex <- x[[2]]
 5 > FL <- x[[4]]
 6 > RW < -x[[5]]
7 > CL <- x[[6]]
8 > CW <- x[[7]]
9 > BD < -x[[8]]
10 > group < - rep(0,200)
11 > group[sex=="M"&colour=="B"] <- 1
12 > group[sex=="F"&colour=="B"] <- 2
13 > group[sex=="M"&colour=="0"] <- 3
14 > group[sex=="F"&colour=="0"] <- 4
15 > group <- factor(group)</pre>
16 > library(MASS)
17 > r <- lda(group~FL+RW+CL+CW+BD,CV=T
18 > sum(r$class!=group)/200
19 [1] 0.05
```

• r\$class is the predicted classes of 200 crabs, group contains the real classes of 200 crabs. So the estimated of misclassification rate is 0.05.

(b) Solution:

```
1 > r <- lda(group~FL+RW+CL+CW+BD)
 2 > r
 3 Call:
 4 lda(group \sim FL + RW + CL + CW + BD)
 6 Prior probabilities of groups:

```

• This crab is very highly possible to be in group 4, so that its sex is female and the colour is orange (which agrees the result of Assignment 2).

(c) Solution:

- The prediction agrees with part (b), which is female and orange.
- The error rate of QDA (0.065) is slightly higher than that of LDA (0.05) based on the leave-one-out cross validation.
- In this particular case, LDA seems better with lower error rate under the same predicted result.
- But we have notice that the LDA is based on an assumption of equal variance-covariance matrices between the input variables of the classes.
